

# Libp2p WebRTC comparative performance tests

Created by **Chinmay Kousik** on Jan 13

## WebRTC Transport Performance Tests

Basic performance tests were run comparing the webrtc transport to the existing tcp transport. There are two test scenarios:

### Scenario 1:

1. Server listens on webrtc or tcp multiaddress.
2. A client dials 10 connections, with 1000 streams per connection to the server.
  - Connections are ramped up at the rate of 1 connection/sec.
  - Streams are created at the rate of 10 streams/sec.
  - This is done to ensure the webrtc transport's inflight request limiting does not start rejecting connections.
1. The client opens streams to the server and runs the echo protocol writing 2KB/s per stream (1 KB every 500ms).

### Scenario 2:

1. Server listens on webrtc or tcp multiaddress.
2. A client dials 100 connections, with 100 streams per connection to the server.
  - Connections are ramped up at the rate of 1 connection/sec.
  - Streams are created at the rate of 10 streams/sec.
  - This is done to ensure the webrtc transport's inflight request limiting does not start rejecting connections.
1. The client opens streams to the server and runs the echo protocol writing 2KB/s per stream (1 KB every 500ms).

Hardware: Both the client and server are AWS [c5.2xlarge](#) instances on the same VPC. The configuration is 8vCPUs and 16GiB RAM.

[Scenario 2] Comparative

Results

- In Scenario 1, where the number of streams to connection ratio is high, WebRTC uses 6 - 7 times more CPU and 3 - 4 times more memory than TCP.
- In Scenario 2, where the number of connections is higher while maintaining the total number of streams, WebRTC uses 4 times as much CPU but memory usage increases to 4 times as much as TCP.
- In Scenario 2, compared to QUIC, WebRTC uses 2.2 times more CPU and 3 times more memory.
